Abstract—In this paper, we study the optimal structure of the source precoding matrix and the relay amplifying matrices for multiple-input multiple-output (MIMO) relay communication systems with parallel relay nodes. We show that both the optimal source precoding matrix and the optimal relay amplifying matrices have a beamforming structure. Using the optimal structure, a joint source and relay power loading algorithm is developed to minimize the mean-squared error (MSE) of the signal waveform estimation. Compared with existing algorithms for parallel MIMO relay networks, the proposed joint source and relay beamforming algorithm has a significant improvement in the system bit-error-rate performance.

I. INTRODUCTION

In order to establish a reliable wireless communication link, one needs to compensate for the effects of signal fading and shadowing. An efficient way to address this issue is to transmit signals through one or multiple relays [1]-[3]. When nodes in the relay system are installed with multiple antennas, we call such system multiple-input multiple-output (MIMO) relay communication system. Recently, MIMO relay communication systems have attracted much research interest and provided significant improvement in terms of both spectral efficiency and link reliability [4]-[15]. Many works have studied the optimal relay amplifying matrix for the source-relay-destination channel. In [7] and [8], the optimal relay amplifying matrix maximizing the mutual information (MI) between the source and destination was derived assuming that the source covariance matrix is an identity matrix. In [9] and [10], the relay amplifying matrix was designed to minimize the mean-squared error (MSE) of the signal waveform estimation at the destination.

A few research has studied the jointly optimal structure of the source precoding matrix and the relay amplifying matrix for the source-relay-destination channel. In [11], both the source covariance matrix and the relay amplifying matrix were jointly designed to maximize the source-destination MI. In [12] and [13], a unified framework was developed to jointly optimize the source precoding matrix and the relay amplifying matrix for a broad class of objective functions.

In [7]-[9] and [13]-[15], the optimal relay amplifying matrix was derived for two-hop MIMO relay networks with a single relay node. In [10] the authors investigated the optimal relay amplifying matrices for two-hop MIMO relay networks with multiple parallel relay nodes. However, the source precoding matrix was not optimized in [10]. In this paper, we propose a jointly optimal source and relay beamforming algorithm which minimizes the MSE of the signal waveform estimation for two-hop MIMO relay communication systems with parallel relay nodes. Our results show that the optimal joint source and relay algorithm has a significant performance improvement over the relay only optimal algorithm developed in [10].

The rest of this paper is organized as follows. The system model is described in Section II. In Section III we study the optimal structure of the source and relay matrices. Section IV shows the simulation results. Conclusion are drawn in Section V.

II. SYSTEM MODEL

Fig. 1 illustrates a two-hop MIMO relay communication system consisting of one source node, K parallel relay nodes, and one destination node. We assume that the source and destination nodes have Ns and Nd antennas, respectively, and each relay node has Nr antennas. The generalization to the system with different number of antennas at each relay node is straightforward. To efficiently exploit the system hardware, each relay node uses the same antennas to transmit and receive signals. Due to its merit of simplicity, we consider the amplify-and-forward scheme at each relay.

Fig. 1. Block diagram of a parallel MIMO relay communication system.
The communication process between the source and destination nodes is completed in two time slots. In the first time slot, the $N_b \times 1$ modulated symbol vector $s$ is linearly precoded as

$$x = Bs \quad (1)$$

where $B$ is an $N_s \times N_b$ source precoding matrix. Without any loss of transmitting power, we assume that $N_b \leq \min(N_s, KN_r, N_d)$. The precoded vector $x$ is transmitted to the relay nodes. The received signal at the $i$th relay node can be written as

$$y_{r,i} = H_{sr,i}x + v_{r,i}, \quad i = 1, \ldots, K \quad (2)$$

where $H_{sr,i}$ is the $N_r \times N_s$ MIMO channel matrix between the source and the $i$th relay node, $y_{r,i}$ and $v_{r,i}$ are the received signal and the additive Gaussian noise vectors at the $i$th relay node, respectively.

In the second time slot, the source node is silent, while each relay node transmits the amplified signal vector to the destination node as

$$x_{r,i} = F_iy_{r,i}, \quad i = 1, \ldots, K \quad (3)$$

where $F_i$ is the $N_r \times N_r$ amplifying matrix at the $i$th relay node. Thus the received signal vector at the destination node can be written as

$$y_d = \sum_{i=1}^{K} H_{rd,i} x_{r,i} + v_d \quad (4)$$

where $H_{rd,i}$ is the $N_d \times N_r$ MIMO channel matrix between the $i$th relay and the destination node, $y_d$ and $v_d$ are the received signal and the additive Gaussian noise vectors at the destination node, respectively.

Substituting (1)-(3) into (4), we have

$$y_d = \sum_{i=1}^{K} H_{rd,i} F_i H_{sr,i} Bs + H_{rd,i} F_i v_{r,i} + v_d$$

$$= H_{rd} F H_{sr} Bs + H_{rd} F v_r + v_d \quad (5)$$

where we define

$$H_{sr} \triangleq [(H_{sr,1})^T, (H_{sr,2})^T, \ldots, (H_{sr,K})^T]^T$$

$$H_{rd} \triangleq [H_{rd,1}, H_{rd,2}, \ldots, H_{rd,K}]$$

$$F \triangleq \text{bd}[F_1, F_2, \ldots, F_K]$$

$$v_r \triangleq [(v_{r,1})^T, (v_{r,2})^T, \ldots, (v_{r,K})^T]^T.$$ 

Here $(\cdot)^T$ denotes the matrix (vector) transpose, $\text{bd}(\cdot)$ stands for a block-diagonal matrix, $H_{sr}$ is a $KN_r \times N_s$ channel matrix between the source node and all relay nodes, $H_{rd}$ is an $N_d \times KN_r$ channel matrix between all relay nodes and the destination node, $v_r$ is obtained by stacking the noise vectors at all the relays and $F$ is the $KN_r \times KN_r$ block diagonal equivalent relay matrix. The diagram of the equivalent MIMO relay system described by (5) is shown in Fig. 2.

By introducing

$$\tilde{F} \triangleq H_{sr} F \quad (6)$$

the received signal vector at the destination can be equivalently written as

$$y_d = \tilde{F} H_{sr} Bs + \tilde{F} v_r + v_d = \tilde{H} s + \tilde{v}$$

where we define $\tilde{H} \triangleq \tilde{F} H_{sr} B$ as the effective MIMO channel matrix of the source-relay-destination link, and $\tilde{v}$ as the equivalent noise with $\tilde{v} \triangleq \tilde{F} v_r + v_d$.

**III. MINIMAL MSE RELAY DESIGN**

Using a linear receiver, the estimated signal waveform vector at the destination node is given by

$$\hat{s} = W^H y_d \quad (7)$$

where $W$ is an $N_d \times N_b$ weight matrix, and $(\cdot)^H$ denotes the matrix (vector) Hermitian transpose. The minimal MSE (MMSE) approach tries to find a weight matrix $W$ that minimizes the statistical expectation of the signal waveform estimation given by

$$\text{MSE} = \text{tr} \left( E \left[ (\hat{s} - s)(\hat{s} - s)^H \right] \right) \quad (8)$$

where $\text{tr}(\cdot)$ stands for the matrix trace, and $E[\cdot]$ denotes statistical expectation. We assume that the source signal vector satisfies $E[ss^H] = I_{N_s}$, where $I_n$ is an $n \times n$ identity matrix, and all noises are independent and identically distributed with zero mean and unit variance. Substituting (7) into (8), we find that the $W$ which minimizes (8) can be written as

$$W = (\tilde{H}\tilde{H}^H + C)^{-1}\tilde{H} \quad (9)$$

where $(\cdot)^{-1}$ denotes the matrix inversion, and $C$ is the equivalent noise covariance matrix written as

$$C \triangleq \tilde{F}\tilde{F}^H + I_{N_d}.$$ 

Using (9), it can be seen that the MSE is a function of $\tilde{F}$ and $B$ and can be written as

$$\text{MSE} = \text{tr} \left( I_{N_b} + \tilde{H}\tilde{H}^H C^{-1} \tilde{H} \right)^{-1}.$$ 

The joint source and relay optimization problem is

$$\min_{\tilde{F}, B} \text{tr} \left( I_{N_b} + \tilde{H}\tilde{H}^H C^{-1} \tilde{H} \right)^{-1} \quad (10)$$

s.t. $\text{tr}(BB^H) \leq P_s \quad (11)$

$$\text{tr}(\tilde{F} [H_{sr} BB^H H_{sr}^H + I_{KN_r}] \tilde{F}^H) \leq P_r \quad (12)$$

where (11) is the transmit power constraint at the source node, while (12) is the power constraint at the output of $H_{rd}$ [10]. Here $P_r > 0$ and $P_s > 0$ are the corresponding power budget.

Let $H_{sr} = U_s A_s V_s^H$ denote the singular value decomposition (SVD) of $H_{sr}$, where the dimensions of $U_s$, $A_s$, $V_s$
are $KN_r \times KN_r$, $KN_r \times N_s$, $N_s \times N_s$, respectively. We assume that the main diagonal elements of $A_s$ are arranged in a decreasing order. Using Theorem 1 in [13], the optimal structure of $H$ and $B$ as the solution to the problem (10)-(12) is given by

$$ F = QA_f U_{s,1}^H, \quad B = V_{s,1} A_b $$

where $Q$ is any $N_d \times N_b$ semi-unitary matrix with $Q^H Q = I_{N_b}$, $U_{s,1}$ and $V_{s,1}$ contain the leftmost $N_b$ columns of $U_s$ and $V_s$, respectively, $A_f$ and $A_b$ are $N_b \times N_b$ diagonal matrices. From (13) we see that the optimal $F$ and $B$ have a beamforming structure. In fact, they jointly diagonalize the source-relay-destination channel $H$. Using (13), the joint source-relay optimization problem (10)-(12) becomes

$$ \begin{align*}
\min_{A_f, A_b} & \quad \text{tr} \left( \left[ I_{N_b} + (A_f A_s A_b) \left( A_f^2 + I_{N_b} \right)^{-1} \right]^{-1} \right) \\
\text{s.t.} & \quad \text{tr}(A_f^2) \leq P_s \\
& \quad \text{tr} \left( A_f^2 (A_s A_b)^2 + I_{N_b} \right) \leq P_r.
\end{align*} $$

Denoting $\lambda_{f,i}, \lambda_{s,i}, \lambda_{b,i}, i = 1, \ldots, N_b$, as the main diagonal elements of $A_f, A_s, A_b$, respectively, the optimization problem (14)-(16) can be equivalently written as

$$ \begin{align*}
\min_{\{\lambda_f, i\}, \{\lambda_s, i\}, \{\lambda_b, i\}} & \quad \sum_{i=1}^{N_b} \left( 1 + \frac{(\lambda_{f,i} \lambda_{s,i} \lambda_{b,i})^2}{\lambda_{f,i}^2 + 1} \right)^{-1} \\
\text{s.t.} & \quad \sum_{i=1}^{N_b} \lambda_{f,i}^2 \leq P_s \\
& \quad \sum_{i=1}^{N_b} \lambda_{f,i}^2 \left( (\lambda_{s,i} \lambda_{b,i})^2 + 1 \right) \leq P_r \\
& \quad \lambda_{b,i} \geq 0, \quad \lambda_{f,i} \geq 0, \quad i = 1, \ldots, N_b.
\end{align*} $$

The problem (17)-(20) is nonconvex and a closed-form solution is intractable to obtain. In the following, we develop an iterative method to obtain a numerical solution of the optimal $\{\lambda_f, i\}$ and $\{\lambda_b, i\}$. Let us define

$$ a_i = \lambda_{s,i}^2, \quad x_i = \lambda_{f,i}^2, \quad y_i = \lambda_{f,i}^2 \left( (\lambda_{s,i} \lambda_{b,i})^2 + 1 \right), \quad i = 1, \ldots, N_b. $$

Then the optimization problem (17)-(20) can be equivalently rewritten as

$$ \begin{align*}
\min_{\{x_i\}, \{y_i\}} & \quad \sum_{i=1}^{N_b} \left( 1 + \frac{a_i x_i y_i}{a_i x_i + y_i} \right)^{-1} \\
\text{s.t.} & \quad \sum_{i=1}^{N_b} x_i \leq P_s \\
& \quad \sum_{i=1}^{N_b} y_i \leq P_r \\
& \quad x_i \geq 0, \quad y_i \geq 0, \quad i = 1, \ldots, N_b.
\end{align*} $$

For a fixed $\{y_i\}$ satisfying (24) and (25), the problem of optimizing $\{x_i\}$ can be written as

$$ \begin{align*}
\min_{\{x_i\}} & \quad \sum_{i=1}^{N_b} \frac{a_i x_i y_i + a_i x_i + y_i + 1}{a_i x_i + y_i + 1} \\
\text{s.t.} & \quad \sum_{i=1}^{N_b} x_i \leq P_s \\
& \quad x_i \geq 0, \quad i = 1, \ldots, N_b.
\end{align*} $$

The Lagrangian function associated with the problem (26)-(28) can be written as

$$ \mathcal{L} = \sum_{i=1}^{N_b} a_i x_i y_i + a_i x_i + y_i + 1 + \mu_1 \left( \sum_{i=1}^{N_b} x_i - P_s \right) $$

where $\mu_1 \geq 0$ is the Lagrangian multiplier. Taking the derivative of (29) with respect to $x_i$ equal to zero, we obtain

$$ x_i = \frac{1}{a_i} \left( \frac{a_i y_i}{\mu_1 (y_i + 1)} - 1 \right), \quad i = 1, \ldots, N_b $$

where $[x]^+ \overset{\text{def}}{=} \max(x, 0)$, and $\mu_1$ is the solution to the following nonlinear equation

$$ \sum_{i=1}^{N_b} \frac{1}{a_i} \left( \frac{a_i y_i}{\mu_1 (y_i + 1)} - 1 \right)^+ = P_s. $$

In a similar fashion, for a fixed $\{x_i\}$ satisfying (23) and (25), we can update $\{y_i\}$ as

$$ y_i = \left( \frac{a_i x_i}{\mu_2 (x_i + 1)} - 1 \right)^+, \quad i = 1, \ldots, N_b $$

where $\mu_2 \geq 0$ is the solutions to the following nonlinear equation

$$ \sum_{i=1}^{N_b} \left( \frac{a_i x_i}{\mu_2 (x_i + 1)} - 1 \right)^+ = P_r. $$

Note that the conditional updates of $\{x_i\}$ and $\{y_i\}$ may either decrease or maintain but cannot increase the objective function in (22). Monotonic convergence of $\{x_i\}$ and $\{y_i\}$ follows directly from this observation. After the convergence of the alternating algorithm, $\lambda_{f,i}$ and $\lambda_{b,i}$ can be obtained from (21) as

$$ \lambda_{f,i} = \sqrt{\frac{y_i}{\lambda_{s,i}^2 x_i + 1}}, \quad \lambda_{b,i} = \sqrt{x_i}, \quad i = 1, \ldots, N_b. $$

And then the optimal structure of $F$ and $B$ is given by (13). From (6), we have $H_{r,d,i} F_i = Q A_f U_{s,i}^H$, where matrix $U_{s,i}^H$ contains the $(i-1)N_r + 1$ to $iN_r$ columns of $U_s^H$. Finally $F_i = (H_{r,d,i})^+ Q A_f U_{s,i}^H, i = 1, \ldots, K$, where $(\cdot)^+$ denotes matrix pseudo-inverse.
IV. SIMULATIONS

In this section, we study the performance of the proposed optimal joint source and relay beamforming algorithm for parallel MIMO relay systems. All simulations are conducted in a flat Rayleigh fading environment using the BPSK constellation, and the noises are i.i.d. Gaussian with zero mean and unit variance. The channel matrices have zero-mean entries with variances $\sigma_s^2/N_s$ and $\sigma_r^2/(KN_r)$ for $H_{sr}$ and $H_{rd}$, respectively. We vary the signal-to-noise ratio (SNR) in the source-to-relay link $SNR_s$ while fixing the SNR in the relay-to-destination link $SNR_d$ to 20dB. We transmit 1000 randomly generated bits in each channel realization, and the bit-error-rate (BER) results are averaged through 200 channel realizations. Here we set $N_b = N_s = N_r = N_d = 3$.

In the first example, we simulate $K = 3$ and compare the BER performance of the proposed joint source and relay algorithm with the naive amplify-and-forward (NAF) algorithm where both the source and relay matrices are scaled identity matrices, and the optimal relay only (ORO) algorithm in [10] which optimizes only the relay amplifying matrices without optimizing the source precoding matrix. From Fig. 3, it can be seen that the NAF algorithm has the worst performance. The proposed algorithm outperforms the other two approaches.

In the second example, we study the effect of the number of relays to the system BER performance using the proposed algorithm. Fig. 4 shows the BER performance with $K = 2, 3, 5$. It can be seen that at BER $= 10^{-3}$, we achieve a 5-dB gain by increasing from $K = 2$ to $K = 5$.

V. CONCLUSIONS

In this paper, we have derived the optimal structure of the source precoding matrix and the relay amplifying matrices for parallel MIMO relay communication systems. The proposed source and relay matrices jointly diagonalize the source-relay-destination channel and minimize the MSE of the signal waveform estimation. The proposed algorithm has an improved BER performance compared with existing techniques.
