Abstract – In this paper, an effective particle swarm optimization (PSO) is proposed for polynomial models for time varying systems. The basic operations of the proposed PSO are similar to those of the classical PSO except that elements of particles represent arithmetic operations and variables of time-varying models. The performance of the proposed PSO is evaluated by polynomial modeling based on various sets of time-invariant and time-varying data. Results of polynomial modeling in time-varying systems show that the proposed PSO outperforms commonly used modeling methods which have been developed for solving dynamic optimization problems including genetic programming (GP) and dynamic GP. An analysis of the diversity of individuals of populations in the proposed PSO and GP reveals why the proposed PSO obtains better results than those obtained by GP.

Keywords Particle swarm optimization, time-varying systems, polynomial modeling, genetic programming

1. Introduction

Genetic programming (GP) [25, 26] is a commonly used evolutionary computation method which is used to generate polynomial models for various systems such as chemical plants [38], time series systems [21], nonlinear dynamic systems [56], object classification systems [1, 65], machine learning systems [27], feature selection systems [43], object detection systems [37], speech recognition systems [11], control systems [5] and mechatronic systems [61]. The GP starts by creating a random initial population of individuals, each of which represents the structure of a polynomial model. Evolution of individuals takes place by mutation and crossover over generations, and individuals with high goodness-of-fit are selected as survivors in the next generation. The evolutionary process continues until the diversity of individuals of a population saturates to a low level or no progress can be found.

Observations reveal that polynomial models represented by individuals in the GP are distinct from each other in early generations. As the GP is progressing, polynomial models represented by individuals converge to a form, which achieves relatively higher goodness-of-fit in the population. Vaessens et al. [59] and Reeves [55] put this population-based optimization method into the context of local searches. Maintaining population diversity in GP is a key to preventing premature convergence and stagnation in local optima [17, 40]. Using GP, it is difficult to develop optimal polynomial models for time-varying systems whose structures or coefficients vary over time while the diversity of individuals in a population is low. Time-varying characteristics can commonly be found in many industrial systems [6, 22, 41, 44, 57, 66, 36, 34]. To develop models for time-varying environments, Wagner et al. [60] developed a GP approach in
which a varying window for capturing significant time series is proposed to generate time series models based on time series data. This approach cannot be applied for generating models for time-varying systems if the nature of the data is not all in time series formats. While mechanisms implemented on evolutionary algorithms have been well studied for solving various dynamic optimization problems [64], those implemented in GP have not been thoroughly studied for the development of polynomial models in time-varying environments. It is essential that an effective algorithm be developed for generating models that deal with time-varying characteristics, given their occurrence in many industrial systems.

Another more recent population based optimization method, particle swarm optimization (PSO) [15], inspires the movements of a population of individuals seeking optimal solutions. The movement of each individual is based on its best position recorded so far from previous generations and the position of the best individual among all the individuals [28, 29]. The diversity of the individuals can be maintained by selecting PSO parameters which provide a balance between global exploration, based on the position of the best individual in the swarm, and local exploration based on each individual’s best previous position. Each individual can move gradually toward both its best position recorded to date and the position of the best individual in the population. Kennedy and Eberhart [29] demonstrated that PSO can solve many difficult optimization problems with satisfactory results. PSO outperforms evolutionary computation methods for solving various static optimization problems [13, 31, 53, 62], and various dynamic optimization problems [2, 9, 8, 52] in which the optima or landscapes of the problems vary over time. Although PSO can obtain satisfactory results when solving various dynamic optimization
problems, PSO has not currently been used on polynomial modelling for time-varying systems. The development of PSO for polynomial modelling for systems with time-varying characteristics is a new research area.

In this paper, a PSO is proposed for the development of polynomial models for time-varying systems in which the system coefficients vary over time. The basic operations of the proposed PSO are identical to those of the classical PSO [12] except that the elements of individuals are represented by arithmetic operations and system variables of polynomial models. The representation of elements takes the form of grammatical swarm [47, 48] or grammatical evolution [46]. The performance of the proposed PSO in the present paper is evaluated by developing models based on several sets of time-varying data which are generated based on time-varying functions with different time varying characteristics. In order to provide a comprehensive evaluation, a comparison is conducted of the results obtained by the proposed PSO with:

(a) classical GP [46] - in which the representation of individuals of population is identical to the one used in the proposed PSO;

(b) dynamic GP - which is integrated with a recent mechanism [63] for solving dynamic optimization problems;

(c) dynamic PSO - which is integrated with a recent mechanism [2] for dynamic optimization problems.

Even if additional computational effort is used in the dynamic PSO to maintain the diversity of individuals, no significant difference in diversity can be found between the proposed PSO and the dynamic PSO. Compared with the two GPs, the results indicate that the proposed PSO outperforms both classical GP and dynamic GP in developing
polynomial models for systems with both time-invariant data and time-varying data. The results can be explained by the diversity of individuals in the proposed PSO, which can be maintained in both early and later generations. The individuals of the proposed PSO continue to explore the solution spaces over the generations. In contrast the individuals of both the GP methods start to converge and get stuck on a solution after early generations.

This paper is organized as follows. Section 2 presents the operations of the proposed PSO. The experimental set-up for testing the proposed PSO, and the data sets used for evaluating the proposed PSO are presented in Sections 3.1 and 3.2 respectively. The experimental results and the analysis of the experimental results are presented in Section 3.3 and 3.4 respectively. Finally, conclusions and suggestions for further work are given in Section 4.

2. Particle swarm optimization

A time-varying system can be formulated as follows:

$$y = f^t(x_1, x_2, \ldots, x_m)$$

(1)

where $y$ is the output response, $x_j, j=1,2,\ldots,m$, is the $j$-th variable of the time-varying system, and $f^t$ is the functional relationship of the time-varying system at time $t$. Based on a set of data which represents relations between the output response $y$ and the variables, $x_1, x_2, \ldots, x_m$ at time $t$, the time-varying system $f^t$ in (1) can be generated in a polynomial form with constant coefficients at time $t$. The data set at time $t$ is defined by

$$D(t) = \{(x^D(t,i), y^D(t,i))\}_{i=1}^{N_D},$$

where the corresponding values of the $i$-th data at time $t$ is

$$x^D(t,i) = (x_1^D(t,i), x_2^D(t,i), \ldots, x_m^D(t,i)) \in \mathbb{R}^m$$

and the corresponding value of the response output of the $i$-th data at time $t$ is $y^D(t,i) \in \mathbb{R}$. Where $D(t)$ is available, $f^t$ can be
generated as the high-order high-dimensional Kolmogorov-Gabor polynomial in expression (2):

\[
y = a_{i_0}(t) + \sum_{i_1=1}^{m_1} a_{i_1}(t)x_i + \sum_{i_1=1}^{m_1} \sum_{i_2=1}^{m_2} a_{i_1,i_2}(t)x_{i_1}x_{i_2} + \sum_{i_1=1}^{m_1} \sum_{i_2=1}^{m_2} \sum_{i_3=1}^{m_3} a_{i_1,i_2,i_3}(t)x_{i_1}x_{i_2}x_{i_3} + ... a_{i_1,...,i_m}(t)\prod_{i_n=1}^{m_n} x_{i_n}
\]

(2)

where \(a_{i_0}(t), a_{i_1}(t), a_{i_2}(t), ..., a_{i_m}(t), a_{i_1,i_2}(t), ..., a_{i_1,...,i_m}(t)\) are the polynomial coefficients at time \(t\). Equation (2) is a universal format of the polynomial model if the number of terms in equation (2) is large enough [18]. In this paper, a PSO is proposed in order to generate the time-varying model at time \(t\) based on equation (2), using an available set of data at time \(t\). Based on [12], the proposed PSO uses a number of individuals, which constitute a swarm, and each individual represents a time-varying model. Each individual traverses the search space to trace the polynomial model of the time-varying system whose system coefficients vary over time.

In the PSO, each individual is represented by the system variables \((x_1, x_2, ..., x_m)\) and the arithmetic operations (‘+’, ‘-‘ and ‘*’) of the system model as defined in (2). \(m\) is the number of variables of the system model. A similar mechanism was first proposed by Kennedy and Eberhart [30] for representing discrete binary variables, and has been applied to the PSO for solving flowshop scheduling problems [31, 51, 58]. The \(i\)-th individual at generation \(g\) is defined as \(P^g_i = (p^g_{i,1}, p^g_{i,2}, ..., p^g_{i,N_p})\); where \(N_p > m\); \(i = 1, 2, ..., N_{pop}\); \(N_{pop}\) is the number of individuals of the swarm; \(N_p\) is the number of elements of the individual; and \(N_{pop}\) is an odd number; \(p^g_{i,k}\) is the \(k\)-th element of the \(i\)-th individual at the \(g\)-th generation, and \(p^g_{i,k}\) is in the range between 0 to 1 i.e. \(p^g_{i,k} \in \{0...1\}\).
If the value of \( N_p \) is large, a larger number of terms can be generated in the model, and the model can better fit the data which is used for model development. However, a model may contain too many unnecessary and complex terms. A complex, over-parameterized model with a large number of parametric terms reduces the transparency and ease of interpretation of the model leading to overfitting problems. To prevent the PSO from generating models which are too complex, the value of \( N_p \) has to be selected carefully.

The value of \( N_p \) can be determined based on the trial and error method, and the value of \( N_p \) cannot be set too high, otherwise redundant terms can be produced. If the number of variables of the system model is 4, \( N_p \) can be initially set as 10. If the modelling error obtained by the PSO is not satisfactory, the value of \( N_p \) can be increased until a satisfactory modelling error is achieved. If the modelling error obtained by the PSO is satisfactory, the value of \( N_p \) can be decreased until just before an unsatisfactory modelling error is achieved.

The elements in odd numbers (i.e. \( p^g_{i,1}, p^g_{i,3}, p^g_{i,5}, \ldots \)) are used to represent the system variables, and the elements in even numbers (i.e. \( p^g_{i,2}, p^g_{i,4}, p^g_{i,6}, \ldots \)) are used to represent the arithmetic operations. For odd \( k \), if \( 0 < p^g_{i,k} \leq \frac{1}{m+1} \), no system variable is represented by the element \( p^g_{i,k} \). If \( \frac{l}{m+1} < p^g_{i,k} \leq \frac{l+1}{m+1} \) with \( l>0 \), \( p^g_{i,k} \) represents the \( l \)-th system variable, \( x_l \). System variables represented by the individual are summarized in Table 1.
Table 1: Representation of system variables

<table>
<thead>
<tr>
<th>The ( k )-th element</th>

</table>

\( k \) is an odd number

In the polynomial model, ‘+’, ‘−’ and ‘∗’ are the only three arithmetic operations considered. For even \( k \), if \( 0 < p_{i,k}^g \leq \frac{1}{3} \), \( \frac{1}{3} < p_{i,k}^g \leq \frac{2}{3} \) and \( \frac{2}{3} < p_{i,k}^g \leq 1 \), the element \( p_{i,k}^g \) represents the arithmetic operations ‘+’, ‘−’ and ‘∗’ respectively. Arithmetic operations represented by the individual are summarized in Table 2.

Table 2: Representation of arithmetic operations

\( k \) is an even number

For example, the \( i \)-th individual at generation \( g \) with 11 elements is used to represent a polynomial model of the time-varying system at time \( t \), which consists of 4 system variables (i.e. \( x_1, x_2, x_3 \) and \( x_4 \)):

\[
\begin{array}{cccccccccccc}
\text{\( p_{i,1}^g \)} & \text{\( p_{i,2}^g \)} & \text{\( p_{i,3}^g \)} & \text{\( p_{i,4}^g \)} & \text{\( p_{i,5}^g \)} & \text{\( p_{i,6}^g \)} & \text{\( p_{i,7}^g \)} & \text{\( p_{i,8}^g \)} & \text{\( p_{i,9}^g \)} & \text{\( p_{i,10}^g \)} & \text{\( p_{i,11}^g \)} \\
0.18 & 0.41 & 0.94 & 0.92 & 0.41 & 0.89 & 0.06 & 0.35 & 0.81 & 0.01 & 0.74 \\
\end{array}
\]

The elements in the individual are within the following ranges:

<table>
<thead>
<tr>
<th>( p_{i,1}^g )</th>
<th>( p_{i,2}^g )</th>
<th>( p_{i,3}^g )</th>
<th>( p_{i,4}^g )</th>
<th>( p_{i,5}^g )</th>
<th>( p_{i,6}^g )</th>
<th>( p_{i,7}^g )</th>
<th>( p_{i,8}^g )</th>
<th>( p_{i,9}^g )</th>
<th>( p_{i,10}^g )</th>
<th>( p_{i,11}^g )</th>
</tr>
</thead>
<tbody>
<tr>
<td>0&lt;</td>
<td>1/3&lt;</td>
<td>4/5&lt;</td>
<td>2/3&lt;</td>
<td>2/5&lt;</td>
<td>0&lt;</td>
<td>0&lt;</td>
<td>4/5&lt;</td>
<td>0&lt;</td>
<td>3/5&lt;</td>
<td>0&lt;</td>
</tr>
<tr>
<td>0.18</td>
<td>0.41</td>
<td>0.94</td>
<td>0.92</td>
<td>0.41</td>
<td>0.08</td>
<td>0.06</td>
<td>0.35</td>
<td>0.81</td>
<td>0.01</td>
<td>0.74</td>
</tr>
<tr>
<td>( \leq 1/5 )</td>
<td>( \leq 2/3 )</td>
<td>( \leq 5/5 )</td>
<td>( \leq 3/3 )</td>
<td>( \leq 3/5 )</td>
<td>( \leq 1/3 )</td>
<td>( \leq 1/5 )</td>
<td>( \leq 5/5 )</td>
<td>( \leq 1/3 )</td>
<td>( \leq 4/5 )</td>
<td></td>
</tr>
</tbody>
</table>
Therefore, the model is represented in the following form:

\[
\begin{array}{cccccccc}
\frac{p_{1,1}^g}{p_{1,2}^g} & p_{1,3}^g & p_{1,4}^g & p_{1,5}^g & p_{1,6}^g & p_{1,7}^g & p_{1,8}^g & p_{1,9}^g & p_{1,10}^g & p_{1,11}^g \\
0 & - & x_4 & * & x_2 & + & 0 & + & x_4 & + \end{array}
\]

which is equivalent to:

\[
\phi_i^g(x) = 0 - x_4 \cdot x_2 + 0 + x_4 + x_3
\]

or

\[
\phi_i^g(x) = -x_4 \cdot x_2 + x_4 + x_3.
\]

The PSO is used only to find the structure of the polynomial and not the coefficients. The system coefficients \( a_0(t), a_1(t), a_2(t) \) and \( a_3(t) \) are determined after the structure of the time-varying model at time \( t \) is established, where the number of coefficients is 4. The completed time-varying model at time \( t \) is represented as follows:

\[
f_i^g(x) = a_0(t) - a_1(t) \cdot x_4 \cdot x_2 + a_2(t) \cdot x_4 + a_3(t) \cdot x_3
\]

In this research, the system coefficients \( a_0(t), a_1(t), a_2(t) \) and \( a_3(t) \) are determined by the orthogonal least squares algorithm (OLSA) [2, 5], which has been demonstrated to be effective in determining system coefficients in polynomial models [39]. Details of the orthogonal least squares algorithm can be found in [3, 7].

The polynomial model represented by each individual is evaluated based on the root mean absolute error (RMAE). This reflects the differences between the predictions by the model of the time-varying system at time \( t \) and the actual values of the data sets at time \( t \). The RMAE of the \( i \)-th individual at the \( g \)-th generation \( RMAE_i^g \) can be calculated based on (3).
where $f^g_i$ is the polynomial model represented by the $i$-th individual $P^g_i$ at the $g$-th generation, \((x^D(t,j), y^D(t,j))\) is the $j$-th data set at time $t$, and $N_D$ is the number of training data sets used for developing the polynomial model of the time-varying system.

The velocity $v^g_{i,k}$ (corresponding to the flight velocity in a search space) and the $k$-th element of the $i$-th individual at the $g$-th generation $p^g_{i,k}$ are calculated by expressions (4) and (5) of the PSO [10] respectively:

\[
v^g_{i,k} = K (v^g_{i,k} + \varphi_1 \cdot \text{rand} \cdot (p_{best_{i,k}} - p^g_{i,k}) + \varphi_2 \cdot \text{rand} \cdot (g_{best} - p^g_{i,k}))
\]

\[
p^g_{i,k} = p^g_{i,k} + v^g_{i,k}
\]

where

\[
p_{best_{i}} = \left[ p_{best_{i,1}}, p_{best_{i,2}}, \ldots, p_{best_{i,N_p}} \right],
\]

\[
g_{best} = \left[ g_{best_{1}}, g_{best_{2}}, \ldots, g_{best_{N_p}} \right],
\]

$k = 1, 2, \ldots, N_p$.

The best previous position so far of an individual is recorded from the previous generation and is represented as $p_{best_{i}}$; the position of the best individual among all the individuals is represented as $g_{best}$; \text{rand}() returns a uniform random number in the range of [0,1]; $w$ is an inertia weight factor; $\varphi_1$ and $\varphi_2$ are acceleration constants [13]; $K$ is a constriction factor derived from the stability analysis of equation (4) to ensure that the
system converges, but not prematurely. $K$ is a function of $\varphi_1$ and $\varphi_2$ as reflected in the following equation:

$$K = \frac{2}{2 - \varphi - \sqrt{\varphi^2 - 4\varphi}}$$

(6)

where $\varphi = \varphi_1 + \varphi_2$ and $\varphi > 4$.

The proposed PSO utilizes $p_{best_i}$ and $g_{best}$ to modify the current search point to prevent the individuals from moving in the same direction, but to converge gradually toward $p_{best_i}$ and $g_{best}$. $g$ is the current generation number, $G$ is the total number of generations [14].

In (4), the particle velocity is limited by a maximum value $v_{max}$. The parameter $v_{max}$ determines the resolution with which regions are to be searched between the present position and the target position. This enhances the local exploration of a search process. If $v_{max}$ is too high, individuals might fly past good solutions. If $v_{max}$ is too small, individuals may not explore sufficiently beyond local solutions. $v_{max}$ was often set as 10%–20% of the dynamic range of the element on each dimension. The pseudo code of the proposed PSO is presented in Figure 1.
3. Polynomial modelling

In this section, the effectiveness of the PSO in modeling time-invariant or time-varying systems is evaluated based on both the time-invariant data and time-varying data. The PSO and the other commonly used, but recently developed, algorithms are compared.

3.1 Time-invariant and time-varying data

For time-invariant data, five sets of data, namely static data, $\Pi_{145}$, $\Pi_{245}$, $\Pi_{345}$, $\Pi_{445}$ and $\Pi_{545}$, were generated based on each of the five benchmark functions, Sphere, Griewank, Rastrigin, Rosenbrock and Ackley (see Table 3) by randomly choosing 100 numbers $X_i$ in each of the predefined intervals $[X_{min}, X_{max}]$. The 100 corresponding output responses $Y_i$...
are computed by the benchmark function $Y_i = F(X_i)$ whose landscape and optimum are static with respect to time. The dimension of each benchmark function is $n=4$. The Sphere ($F_{sph}$) and Rosenbrock ($F_{ros}$) functions are unimodal (a single local and global optimum), and the Griewank ($F_{gri}$), Rastrigin ($F_{ras}$), and Ackley ($F_{ack}$) functions are multimodal (several local optima).

Table 3: Benchmark functions and initialization areas

<table>
<thead>
<tr>
<th>Benchmark functions</th>
<th>Initialization areas</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sphere ($Sph$): $F_{sph}(x) = \sum_{i=1}^{n} x_i^2$</td>
<td>$[-50,50]^n$</td>
</tr>
<tr>
<td>Rosenbrock ($Ros$): $F_{ros}(x) = \sum_{i=1}^{n} [100(x_{i+1}^2 - x_i^2)^2 + (x_i - 1)^2]$</td>
<td>$[-30,30]^n$</td>
</tr>
<tr>
<td>Rastrigin ($Ras$): $F_{ras}(x) = \sum_{i=1}^{n} (x_i^2 - 10 \cos(2\pi x_i) + 10)$</td>
<td>$[-5.12,5.12]^n$</td>
</tr>
<tr>
<td>Griewank ($Gri$): $F_{gri}(x) = \frac{1}{4000} \sum_{i=1}^{n} x_i^2 - \prod_{i=1}^{n} \cos\left(\frac{x_i}{\sqrt{i}}\right) + 1$</td>
<td>$[-600,600]^n$</td>
</tr>
<tr>
<td>Ackley ($Ack$): $F_{ack}(x) = -20 \cdot \exp\left(-0.2 \sqrt{\frac{1}{n} \sum_{i=1}^{n} x_i^2}\right) - \exp\left(\frac{1}{n} \sum_{i=1}^{n} \cos(2\pi x_i)\right) + 20 + e$</td>
<td>$[-32,32]^n$</td>
</tr>
</tbody>
</table>

The time-varying data used in this study was generated by a set of time-varying functions which were extended from the benchmark functions shown in Table 3. $X_i$ was generated by randomly chosen numbers in the predefined interval of the benchmark function. $Y_i$ was computed in each generation of the PSO run by the time-varying function $Y_i = F(X_i, t)$ whose landscape or optima varies over time $t$. The mechanisms for
the development of the time-varying functions were based on the dynamic properties of step changes of optima, changes of locations of optima, and changes of the landscapes of the benchmark functions [33, 42].

For those based on the mechanism of step changes of optima, the time-varying data was generated based on each of the five benchmark functions, $F_{\text{Sp}}$, $F_{\text{Ro}}$, $F_{\text{Ra}}$, $F_{\text{G}}$, and $F_{\text{A}}$. The optimum position $\mathbf{x}^*$ of each benchmark function is moved by adding or subtracting random values in all dimensions by a severity parameter $s$, at every change of the environment [32]. The choice of whether to add or subtract the severity parameter $s$ on the optimum $\mathbf{x}^*$ is done randomly with an equal probability. The severity parameter $s$ is defined by:

$$s = \begin{cases} +\Delta d \cdot (X_{\text{max}} - X_{\text{min}}) & \text{if } \text{rand}(\cdot) \geq 0 \\ -\Delta d \cdot (X_{\text{max}} - X_{\text{min}}) & \text{if } \text{rand}(\cdot) < 0 \end{cases}, \quad (7)$$

where $\Delta d$ determines the scale of the step change of optima.

For each test run, a different random seed was used. The severity was chosen relative to the extension (in one dimension) of the initialization area of each benchmark function. The optima of the benchmark functions were periodically changed in every 100 generations of the runs of the algorithms. For small step changes of optima, $\Delta d = 5\%$ is selected, and five sets of time-varying data, (namely step move data with $\Delta d = 5\%$, $\Pi_{\text{Sp}}^{5\%}$, $\Pi_{\text{Ro}}^{5\%}$, $\Pi_{\text{Ra}}^{5\%}$, $\Pi_{\text{G}}^{5\%}$ and $\Pi_{\text{A}}^{5\%}$) were generated based on the five benchmark functions, $F_{\text{Sp}}$, $F_{\text{Ro}}$, $F_{\text{Ra}}$, $F_{\text{G}}$ and $F_{\text{A}}$, in Table 3 respectively. For large step changes of optima, $\Delta d = 10\%$ is selected, and five sets of time varying data, (namely step move data with $\Delta d = 5\%$, $\Pi_{\text{Sp}}^{10\%}$, $\Pi_{\text{Ro}}^{10\%}$, $\Pi_{\text{Ra}}^{10\%}$, $\Pi_{\text{G}}^{10\%}$ and $\Pi_{\text{A}}^{10\%}$) were generated respectively.
For those based on the mechanism of changes of locations of optima [21], the time-varying data was generated based on the following time-varying function:

$$F(x) = w(t) \cdot F_i(x) - (1.0 - w(t)) \cdot F_i(x + s)$$

(8)

where

$$w(t) = 1 - \frac{100}{G} \text{floor}\left(\frac{t}{100}\right), \quad 0 \leq t \leq G; \quad G$$ is the pre-defined number of generations;

$$F(x)$$ is any of the five benchmark functions, $$F_{\text{sph}}, F_{\text{ros}}, F_{\text{ras}}, F_{\text{gri}}$$ and $$F_{\text{ack}}$$, in Table 3, $$s$$ is a randomly chosen constant which is 20% of the range of the benchmark function $$F_i(x)$$. The optimum in $$F(x)$$ shifts from the original optimum $$x^*$$ of $$F_i(x)$$ to the new optimum $$(x^* + s)$$ in every 100 generations. Based on these time-varying functions, five sets of time varying data, namely shift data, $$\Pi_{\text{sph}}^{\text{shift}}$$, $$\Pi_{\text{ros}}^{\text{shift}}$$, $$\Pi_{\text{ras}}^{\text{shift}}$$, $$\Pi_{\text{gri}}^{\text{shift}}$$ and $$\Pi_{\text{ack}}^{\text{shift}}$$, were generated based on the five benchmark functions, $$F_{\text{sph}}, F_{\text{ros}}, F_{\text{ras}}, F_{\text{gri}}$$ and $$F_{\text{ack}}$$ in Table 3 respectively.

For those based on the mechanism of changes of the landscapes of the benchmark functions [24], the time-varying data was generated based on the following time-varying function, which is similar to equation (8):

$$F(x) = w(t) \cdot F_i(x + s) - (1.0 - w(t)) \cdot F_j(x)$$

(9)

where $$F(x)$$ is any of the five benchmark functions in Table 3, and $$F_j(x)$$ is another benchmark function. The landscape of $$F(x)$$ changes gradually from the landscape of $$F_i(x)$$ to the landscape of $$F_j(x)$$ in every 100 generations. $$s$$ is a randomly chosen constant which is 20% of the range of the benchmark function $$F_i(x)$$. Based on the time-varying function (10), four sets of time varying data, namely match data, $$\Pi_{\text{sph}}^{\text{match}}$$, $$\Pi_{\text{ros}}^{\text{match}}$$, $$\Pi_{\text{gri}}^{\text{match}}$$ and $$\Pi_{\text{ack}}^{\text{match}}$$, were generated in which $$F_{\text{sph}}$$ is used as $$F_j(x)$$, and $$F_{\text{ros}}, F_{\text{ras}}, F_{\text{gri}}$$ or $$F_{\text{ack}}$$
functions is used as \( F(x) \). Another three sets of match data, \( \Pi_{\text{match}}^{\text{Ros-Ras}} \), \( \Pi_{\text{match}}^{\text{Ros-Gri}} \) and \( \Pi_{\text{match}}^{\text{Ros-Ack}} \), were generated in which \( F_{\text{Ros}}(x) \) is used as \( F(x) \), and \( F_{\text{Ros}}, F_{\text{Gri}}, \) or \( F_{\text{Ack}} \) is used as \( F(x) \).

A brief summary of all the 27 data sets is presented in Table 4, and the benchmark functions, which can be used to generate the data sets, can be downloaded from the following link (http://www.4shared.com/account/dir/G2J--2eV/sharing.html).

3.2 Experiment Set-up

In this paper, because the basic operation of the PSO discussed in Section 2 is similar to classical PSO, it is called classical PSO, C-PSO in this paper. The following parameters, which can be found in reference [48], were implemented in the C-PSO: the number of particles in the swarm was 100; the number of elements in the particle was 30; both the acceleration constants $\phi_1$ and $\phi_2$ were set at 2.05; the maximum velocity $v_{\text{max}}$ was 0.2; the pre-defined number of generations was 1000. Based on the results in [48], these parameters can produce satisfactory results when solving both parameterized and combinatorial problems. Therefore, these parameters are used in this research. The C-PSO was compared against the following five approaches for generating models based on both the time-invariant and time-varying data sets, which have been discussed in Section 3.1.

1. Classical genetic programming (C-GP): A commonly used method for polynomial modeling, the classical genetic programming (C-GP) [25, 26] was employed. Here the representation of the individuals of the grammatical genetic programming [46] is identical to the one of the representations of the C-PSO. The basic operations of the C-GP are shown in Figure 2 in the Appendix. The C-GP first starts by creating a random initial population $\Omega(g)$ of individuals $[\theta_1(g), \theta_2(g), \ldots, \theta_{\text{POP}}(g)]$, while $g=0$. The $i$-th individual $\theta_i(g)$ at the $g$-th generation represents the structure of the time-varying model (2). For example, the $i$-th individual at the $g$-th generation $\theta_i(g)$ represents the structure of the following time-varying model at time $t$:

$$\theta_i(g) = x_1^2 - x_2^2 + x_1 \cdot x_2 \cdot x_4$$

(10)
After determining the structure of the time-varying model $\theta_i(g)$, the system coefficients are determined. The completed time-varying model $\theta_i(g)'$ is represented by:

$$\theta_i(g)' = a_0(t) + a_1(t)x_1^2 - a_2(t)x_2^2 + a_3(t)x_1x_2x_4 \quad (11)$$

where $a_0(t)$, $a_1(t)$, $a_2(t)$ and $a_3(t)$ are the system coefficients at time $t$, and are calculated by OLSA. This is the same as the one used in the C-PSO for calculating system coefficients. The classical genetic operations, point mutation and one-point crossover, were used. Standard roulette wheel selection was used. The following GA parameters were implemented in the C-GP: The population size is 100. The type of replacement is elitist. Crossover rate and mutation rate were 0.9 and 0.01 respectively. The pre-defined number of generations was 1000. The dimension of the individuals was 30.

2. Dynamic particle swarm optimization (D-PSO): D-PSO is identical to the C-PSO except for integration of the recent mechanisms for maintaining diversities of the swarms [2] when solving the dynamic optimization problem. The mechanism splits the whole set of particles into a set of interacting swarms. These swarms interact locally through an exclusion parameter and globally through an anti-convergence operator. Each swarm maintains its diversity by using either charged or quantum particles. Results show that when this mechanism for maintaining diversity in the PSO is used, the PSO outperforms the other PSO or evolutionary algorithms, even where they are integrated with other diversity maintaining mechanisms, for solving dynamic optimization problems. The performance of D-PSO was optimized by tuning
it with different settings for the number particles in the sub-swarms. 5, 10 and 25 particles in the sub-swarms were used and the best performance among them was recorded. The detailed description of the mechanisms used to maintain diversity in the swarms can be found in [2].

3. Dynamic genetic programming (D-GP): D-GP is identical to the C-GP except for integration of the recent mechanism [63] used for evolutionary algorithms on solving dynamic optimization problems. The mechanism relocates the positions of the individuals based on the changes of the landscape of the dynamic optimization problem and the average sensitivities of their decision variables to the corresponding change in the landscape. While integrating the mechanism in the evolutionary algorithm, the evolutionary algorithm outperforms the other dynamic evolutionary approaches for solving dynamic optimization problems. The detailed description of the mechanisms for maintaining diversity can be found in [63].

4. Polynomial-genetic algorithm (P-GA): P-GA is a genetic algorithm proposed by Potgieter and Engelbrecht [53] which can evolve structurally polynomial expressions in order to accurately describe a given data set. In P-GA, each individual is used to represent the structure of the polynomial and this is evolved based on the designed crossover and mutation operations. The coefficients of the polynomial are determined by OLSA [3, 7]. The crossover rate and the mutation rate were set at 0.1 and 0.2 respectively, which are the same as those used in [54]. The population size was set at 100. The individual length was set at 22.
5. Polynomial neural network (PNN): PNN is developed based on a genetic algorithm which is proposed by Oh and Pedrycz [50]. Individuals in the genetic algorithm are used to represent the parameters of the PNN including the number of input variables, the order of the polynomial and input variables, which lead to a structurally and parametrically optimized network. The coefficients of the polynomial are determined by OLSA [3, 7]. The number of layers of the PNN was set at 3. The crossover rate and the mutation rate used in the genetic algorithm were set at 0.65 and 0.1 respectively, which are the same as those used in [50]. The population size was set at 100. The individual length was set at 36.

3.3 Experimental results

Thirty runs were performed on the C-PSO, D-PSO, D-GP, C-GP, P-GA and PNN in generating polynomial models based on each of the 27 data sets shown in Table 4. In each generation of the runs, the RMAE obtained by the individuals of the six algorithms was recorded.

Online performance of the algorithms is demonstrated by the convergence plots. Figures 3a, 3b, 3c, 3d and 3e show the convergence plots for the step move data with $\Delta d = 5\%$ ( $\Pi_{sk}^{5}$, $\Pi_{do}^{5}$, $\Pi_{dr}^{5}$, $\Pi_{do}^{5}$, $\Pi_{sk}^{5}$) respectively. It can be observed from Figures 3a-3e that the evolutionary algorithms, C-GP, D-GP, P-GA and PNN, converged more quickly in the early generations than did those of the PSO algorithms, C-PSO and D-PSO. However, the PSO algorithms, C-PSO and D-PSO, kept progressing after the early generations. Finally, both the PSO algorithms, C-PSO and D-PSO, reached a
smaller RMAE than that reached by the evolutionary algorithms, C-GP, D-GP, P-GA and PNN, in the final stage of the search. D-PSO can reach the smallest RMAE compared with those obtained by the other algorithms. Therefore in general, the PSO algorithms outperform the evolutionary algorithms in generating the models for these static data sets in later generations. For the rest of the data (static data, step move data with $\Delta d = 10\%$, shift data, match data based on $F_{sd}$, match data based on $F_{sw}$), a similar finding can be observed in that the convergence speed of the evolutionary algorithms was faster than that of the particle swarm optimization algorithms in the early generations. In the late generations, the particle swarm optimization algorithms can reach a smaller RMAE than that reached by the evolutionary algorithms.

The smallest RMEA among all generations of each run of each algorithm was recorded, and was averaged. This measure is called offline performance. The commonly used method for testing the significance of the results, the Wilcoxon Rank Sum Test, was used to compare the results between the two algorithms [19]. The results of the 30 runs for two algorithms form two independent random samples $X$ and $Y$. The distributions of $X$ and $Y$, $F_X$ and $F_Y$, are compared using the null-hypothesis $H_0$: $F_X=F_Y$ and the one-sided alternative $H_1$: $F_X<F_Y$. We performed the significance tests at a significance level $\alpha = 0.01$. Only if the probability of the observed difference is less than $\alpha$, is the null-hypothesis rejected and the alternative hypothesis accepted. The significance comparison among a set of the six algorithms, C-PSO, D-PSO, D-GP, C-GP, P-GA and PNN, is displayed using a $6 \times 6$ matrix, where ‘X’ denotes that the result obtained by algorithm $i$ and that obtained by algorithm $j$ is statistically significant different. $i$ and $j$ are the position in the corresponding result table. An entry of ‘_’ indicates that the result
obtained by algorithm \( i \) and algorithm \( j \) is not a statistically significant difference. We name such a matrix a significance matrix.

Tables 5, 6, 7, 8, 9 and 10 show the performance and the significance matrices for the static data, the step move data with \( \Delta d = 5\% \), the step move data with \( \Delta d = 10\% \), the shift data, the match data based on \( F_{spa} \) and the match data based on \( F_{ras} \) respectively. The average RMAE among the 30 runs of each algorithm and the ranks of the algorithms in regard to the average RMAE are shown in the tables. Table 5 shows that D-PSO is better than C-PSO in generating time-invariant models based on the static data \( \Pi_{spa}^{stat} \). C-PSO is better than D-GP which is better than C-GP, P-GA and PNN. A significant difference can be found between the results obtained by the PSO algorithms (C-PSO and D-PSO) and those obtained by the evolutionary algorithms (D-GP, C-GP, P-GA and PNN). However, there is no significant difference between the results obtained by C-PSO and D-PSO, even if D-PSO can obtain a smaller RMAE than that obtained by C-PSO. In regard to the other static data sets \( \Pi_{ras}^{stat}, \Pi_{ras}^{stat}, \Pi_{Gri}^{stat}, \Pi_{Ack}^{stat} \), both the PSO algorithms, C-PSO and D-PSO can obtain a smaller average RMAE than that obtained by the evolutionary algorithms, D-GP, C-GP, P-GA and PNN. Also, significant differences exist between the results obtained by the PSO algorithms (C-PSO and D-PSO) and those obtained by the evolutionary algorithms (D-GP, C-GP, P-GA and PNN). Also, similar results can be found in Tables 6, 7, 8, 9 and 10 where the PSO algorithms are significantly better than the evolutionary algorithms in generating models based on the time-varying data.

Therefore, it can be concluded that the PSO algorithms are significantly better than the evolutionary algorithms.
3.4 Population diversity

An investigation of population diversities of C-PSO, D-PSO, D-GP, C-GP, P-GA and PNN is presented in this section. Maintaining population diversity in population-based algorithms like evolutionary algorithms or PSO is a key to preventing premature convergence and stagnation in local optima [11, 16, 40]. Thus it is essential to study the population diversities of the six algorithms during the search. Various diversity measures, which involve calculations of distance between two individuals in genetic programming for the development of models, have been widely studied [4, 49]. These distance measures calculate the distances between two individuals which are in a tree based representation in genetic programming. They indicate the number of different nodes and different terminals between two individuals. In this paper, we measure the distance between two individuals by counting the number of different terms of the polynomials represented by the two individuals in the four algorithms. If the terms in both polynomials are all identical, the distance between the two polynomials is zero. The distance between the two polynomials is larger when the number of different terms in the two polynomials is larger. For example, $f_1$ and $f_2$ are two polynomials represented by:

$$f_1 = x_1 + x_2 + x_1 \cdot x_3 + x_4^2 + x_1 \cdot x_3 \cdot x_5$$

and

$$f_2 = x_1 + x_2 + x_1 \cdot x_5 + x_4 + x_1 \cdot x_3 \cdot x_5$$

Both $f_1$ and $f_2$ contain the three terms $x_1$, $x_2$ and $x_1 \cdot x_3 \cdot x_5$, and the terms $x_1 \cdot x_3^2$ in $f_1$ and the terms $x_1 \cdot x_5$ and $x_4$ in $f_2$ are different. Therefore, the number of terms which are different in $f_1$ and $f_2$ are 2, and the distance between $f_1$ and $f_2$ is defined to be 2.
The diversity measure of the population at the \( g \)-th generation is defined by the total sum of distances of individuals which is denoted as:

\[
\sigma_g = \sum_{i=1}^{N} \sum_{j=1}^{N} d(s_g(i), s_g(j))
\]

where \( s_g(i) \) and \( s_g(j) \) are the \( i \)-th and the \( j \)-th individuals in the population at the \( g \)-th generation, and \( d \) is the distance measure between the two individuals.

The diversities of the populations throughout the generations were recorded for the four algorithms. Figure 4 shows the diversity plots which indicate the diversities of the individuals in the algorithms in generating the models based on the step move data with \( \Delta d = 5\% \). Figure 4a, 4b, 4c, 4d and 4e shows the diversities for static data which are generated based on the benchmark functions \( SphF \), \( RosF \), \( RasF \), \( GriF \) and \( AckF \) respectively.

The diversities of the populations throughout the generations were recorded for the six algorithms. The five figures indicate that the diversities along the generations of the D-PSO are slightly higher than those of the C-PSO which are much higher than those of the evolutionary algorithms, D-GP, C-GP, P-GA and PNN. For the rest of the data (static data, step move data with \( \Delta d = 10\% \), shift data, match data based on \( F_{q_{st}} \), match data based on \( F_{q_{st}} \), similar findings indicate that the diversities of the two PSO algorithms are much larger than those of the evolutionary algorithms.

The findings indicate the reason why the PSO algorithms, D-PSO and C-PSO can obtain significantly better results than the evolutionary algorithms, D-GP, C-GP, P-GA and PNN. The diversities of the individuals of the PSO algorithms can be maintained along the search in both earlier and later generations, while the individuals of the evolutionary algorithms converged in the earlier generation. Therefore, the PSO
algorithms are more likely to explore the solution space, as the diversity of the individuals of the algorithms can be maintained. In regard to the effectiveness of the two PSO algorithms, since the diversities of the populations of C-PSO are only slightly smaller than those of the D-PSO, D-PSO can obtain only slightly better results than those obtained by C-PSO.

4 Conclusion and further work

In this paper, a particle swarm optimization algorithm has been proposed for developing polynomial models in which both time-invariant and time-varying characteristics are represented. The individuals of the PSO are represented by arithmetic operations and system variables, which are the components of the polynomial models. A set of dynamic benchmark functions whose optima or landscapes vary over time was employed to evaluate the performance of the PSO. The PSO algorithms, C-PSO and D-PSO, were used to generate models based on both the time-invariant and time-varying data sets. The evolutionary algorithms, D-GP, C-GP, P-GA and PNN, were also included in the experiments for comparison. Results show that the PSO algorithms significantly outperform the evolutionary algorithms in generating models based on both the time-invariant or time-varying data sets. It is observed that the evolutionary algorithms converge faster in the earlier generations when compared with the PSO algorithms. In contrast, the PSO algorithms can obtain better solutions in the later generations of the runs. The performance obtained in the results can be explained by the diversity measures and the fact that significant differences of diversities between the PSO algorithms and the evolutionary algorithms exist.
In future work, we will enhance the effectiveness of the PSO by the hybridization of the evolutionary algorithm and the PSO algorithm. Here the evolutionary algorithm will be implemented to localize the potential solutions in the early generations and the PSO algorithm will be implemented in order to continue to explore the solution space to avoid pre-mature convergence in late generations. The resulting algorithm will be further validated by solving real-time traffic flow forecasting problems, which are time varying in nature.
